Theory

Assumptions

- ▶ Conduction within cap rock rapidly wipes out any sharp temperature differences. Thus, temperature in cap rock varies smoothly.
- ▶ Longitudinal heat conduction in cap rock can be neglected due to high Peclet numbers.
- ▶ Temperature profile can be adequately approximated by any reasonably flexible function with a few parameters.

Equations

Fitting function:

$$T(t, z) = T_0 + (\theta + pz + qz^2)e^{-z/d}$$

- ▶ θ is temperature difference between temperature at interface between reservoir and cap/base rock and that at infinity (T_0), i.e.,
 $\theta = T_r(t) - T_0$.
- ▶ p, q are model fit parameters to be determined.
- ▶ z is vertical distance from reservoir.
- ▶ d is the “diffusion length” given by $d = \frac{\sqrt{kt}}{2}$; k is thermal diffusivity of cap/base rock.

Determining model parameters

Heat flow into cap rock:

$$\frac{\partial T}{\partial t} = k \frac{\partial^2 T}{\partial z^2}$$

- ▶ At the interface, this yields $\frac{\partial \theta}{\partial t} = k \frac{\partial^2 T}{\partial z^2} \Big|_{z=0}$.
- ▶ Inserting the assumed function for T into this and finite differencing for time derivatives yields

$$\frac{\theta - \theta^n}{\Delta t} = k \left(\frac{\theta}{d^2} - \frac{2p}{d} + 2q \right)$$

where θ^n is interface temperature at beginning of time step.

Determining model parameters

Conservation of cap rock energy:

$$\frac{\partial}{\partial t} \int_0^\infty T dz = k \left. \frac{\partial T}{\partial z} \right|_0^\infty.$$

- ▶ Again inserting the assumed function for T , this yields

$$\frac{\theta d + p d^2 + 2q d^3 - I^n}{\Delta t} = k \left(\frac{\theta}{d} - p \right),$$

where $I^n = \theta^n d^n + p^n (d^n)^2 + 2q^n (d^n)^3$.

Determining model parameters

Eliminating q from heat flow & energy balance yields:

$$p = \frac{\frac{k\theta\Delta t}{d} + I^n - d^3 \frac{(\theta - \theta^n)}{k\Delta t}}{3d^2 + k\Delta t}$$

$$q = \frac{(2pd - \theta + d^2 \frac{(\theta - \theta^n)}{k\Delta t})}{2d^2}$$

The heat loss rate is:

$$-\lambda \frac{\partial T}{\partial z} \Big|_{z=0} = \lambda \left(\frac{\theta}{d} - p \right).$$

The energy stored in cap rock is given by:

$$E_c = \frac{\lambda}{k} \int_0^\infty T dz = \frac{\lambda}{k} (\theta + pd + 2qd^2).$$

Hysteresis in multiphase flow

- Introduction**

- Numerical Example

CO₂ Benchmarks

- Results

Theory

Definition. Dependence of capillary pressures and relative permeabilities (in immiscible multiphase flow systems), on phase saturation is generally multivalued and based on wetting history. This phenomena is called “hysteresis”.

- ▶ Commonly observed following fluid saturation path reversals.
- ▶ Attributed to effects such as contact angle, irregular pore geometry and non-wetting fluid entrapment.
- ▶ Several models exist for hysteresis [Snell 1962, Land 1968, Lenhard-Parker & Parker-Lenhard 1987, Delshad *et al* 1987-1989-2000].
- ▶ Can yield significantly different results in cyclic injection of CO₂ scenarios.

Schematic

Primary/Secondary Drainage/Imbibition curves

- ▶ Modeling hysteretic behavior requires accounting for non-wetting fluid entrapment.
- ▶ As wetting fluid moves into larger channels during imbibition, non-wetting fluid is entrapped.
- ▶ Entrapped non-wetting fluid is separated from continuous non-wetting fluid
- ▶ An apparent saturation is used to account for non-wetting fluid entrapment, $\bar{\bar{S}}_w = \bar{S}_w + \bar{S}_{nt}$.

Example of hysteresis model - Land's method

Predicts amount of non-wetting fluid trapped in pore spaces by an empirical-graphical method

- ▶ Effective phase saturations are given by

$$\bar{S}_w = \frac{S_w - S_m}{1 - S_m}; \bar{S}_n = \frac{S_n}{1 - S_m}.$$

- ▶ Land's algorithm is given by the empirical formula for the effective residual non-wetting phase saturation

$$\bar{S}_{nr} = \frac{1 - \Delta \bar{S}_w}{1 + R_{nw}(1 - \Delta \bar{S}_w)}, \quad R_{nw} = \frac{1}{\bar{S}_{nr}^0} - 1.$$

- ▶ Effective entrapped non-wetting fluid saturation is then linearly interpolated ($\bar{S}_{nt} = 0$, \bar{S}_{nr} @ $\bar{S}_w = \Delta \bar{S}_w$, 1 resply.) by $\bar{S}_{nt} = \bar{S}_{nr} \left(\frac{\bar{S}_w - \Delta \bar{S}_w}{1 - \Delta \bar{S}_w} \right)$, $\bar{S}_w \geq \Delta \bar{S}_w$.

Figure: Land's method

Land's method

Implications

- ▶ In modeling hysteretic fluid flow, when $\bar{\bar{S}}_w < \Delta \bar{S}_w$, main drainage is followed and $\Delta \bar{S}_w$ is updated to $\bar{\bar{S}}_w$.
- ▶ As interfaces between non-wetting and wetting fluids advance into larger-sized pores, non-wetting fluid is entrapped (discontinuous).
- ▶ As the interfaces advance into smaller-sized pores, non-wetting fluid is released (into continuous phase) in identical amounts.
- ▶ In this way, hysteresis is ignored in dependence between \bar{S}_{nt} and $\bar{\bar{S}}_w$

Figure: Land's method

Relative permeability, capillary pressure expressions

Aq. phase relative permeability (BCB)

$$k_{rw} = \bar{S}_w^{\frac{2+3\lambda}{\lambda}}$$

Non-aq. phase relative permeability (BCB)

$$k_{rn} = k_{rn}^0 (1 - \bar{S}_w)^2 (1 - \bar{S}_w^{\frac{2+\lambda}{\lambda}})$$

Capillary pressure (BCB)

$$p_c = p_d \bar{S}_w^{\frac{-1}{\lambda}}$$

CO₂ Benchmarks

Results

Cyclic injection of CO₂ in aquifer

- ▶ 2500 m long aquifer at depth of 9000 ft, saturated with water.
- ▶ 1-d approximation, with 100 elements.
- ▶ CO₂ injected at 250 mscf/d at one end. BHP specified producer.
- ▶ Gas injection turned off every 100 days and water injected in place. (WAG with 100 day cycle).
- ▶ 1000 day simulation end time.

- Results

CO₂ injection in slanted aquifer

Features

- ▶ Slanted reservoir @1% dip.
- ▶ Dimensions of 100 km × 100 km × 50 m
- ▶ Horizontal well at bottom of reservoir injecting CO₂ @1 Mt/y.
- ▶ Injection period is 20 years...monitored to infinity.
- ▶ Interested in CO₂ distribution in phases with time and time of immobility.
